Clinical trials with ambulatory blood pressure monitoring : fewer patients needed?
... pressure reduction at a given time (eg, the time of peak plasma concentration) and the blood pressure changes at all other times.
It has also been suggested that ambulatory monitoring may facilitate the conduct of clinical trials by the early identification and exclusion of subjects whose blood pressure is raised only in the clinic environment (white coat reactors).[19,26] This feature...

ABSTRACT: Monitoring clinical trials often requires examining the interim findings to see if the **sample** size originally specified in the **protocol** will provide the required power against the null hypothesis when the alternative hypothesis is true, and to increase the sample size if necessary. This paper presents a new method, based on the overall response rate, for carrying out interim power evaluations when the observations have binomial distributions, without unblinding the treatment **assignments** of materially affecting the type I error rate. Simulation study results confirm the performance of the method.

Objective: To determine whether home care givers can accurately measure plasma sodium in children with diabetes insipidus (DI) by using an I-STAT portable clinical analyzer (PCA) and to collect preliminary data on home PCA use. Study design: Care givers of 4 children with DI and impaired thirst or inability to access water freely were instructed in PCA use. During an initial preclinical phase, the accuracy of sodium concentration measured by care givers was assessed by comparison to simultaneous analysis in a clinical laboratory. Participants were subsequently randomly assigned to daily home PCA monitoring or routine care. All participants crossed over from their original randomized group **assignment** to the alternate group. Results: After a single education session, all care givers were able to perform PCA testing. There was good correlation between PCA and laboratory sodium ($r = 0.92$). On the basis of Error Grid Analysis, use of the PCA sodium would have resulted in treatment decisions identical to those made based on the laboratory sodium value in 62 of 66 instances. Four minor differences in treatment would have occurred. There was no statistically significant difference in clinical outcome during daily monitoring versus routine care. Conclusions: Results obtained by care givers using the PCA are sufficiently reliable for assessment of fluid status and making treatment decisions.

OBJECTIVE: To determine the incidence of culture positivity in intravascular monitoring systems by comparing 48- versus 72-hour intervals for flush solution, stopcocks, and catheters on removal. DESIGN: Prospective, quasi-experimental, random **assignment** . SETTING: Intensive care units of a midwestern university medical center and a community hospital. PATIENTS: Seventy-six critically ill adult patients, ranging in age from 24 to 96 years ($X = 61.6$), requiring arterial or pulmonary artery

catheters. OUTCOME MEASURE: Culture positivity of flush solution, stopcocks, or catheter tips. INTERVENTION: Data collection was initiated at designated change intervals of 48- or 72-hours; cultures were taken of flush solution and stopcocks; catheter tip cultures were obtained on catheter removal. RESULTS: Chi-square analyses indicated that increasing the change interval to 72 hours resulted in no significant difference in culture positivity of catheter tips. However, the difference between the 48- and 72-hour groups in culture-positivity rates of stopcocks from arterial catheters was significant (1, N = 82) = 6.86, p less than 0.01. CONCLUSIONS: Our results showed that increasing the change interval to 72 hours did not increase the risk of catheter-associated infection or catheter-associated bacteremia. Chi-square analysis did not show an association between culture-positive stopcocks, the incidence of culture-positive catheter tips, entries into the system, or catheter-related bacteremia and a change interval that was increased to 72 hours. Thus, increasing the change interval to 72 hours does not increase the risk of infection.

NUMBER OF REFERENCES: 36

Background Previous trials have suggested that calcium supplementation during pregnancy may reduce the risk of preeclampsia. However, differences in study design and a low dietary calcium intake in the populations studied limit acceptance of the data. Methods. We randomly assigned 4589 healthy nulliparous women who were 13 to 21 weeks pregnant to receive daily treatment with either 2 g of elemental calcium or placebo for the remainder of their pregnancies. Surveillance for preeclampsia was conducted by personnel unaware of treatment-group assignments, using standardized measurements of blood pressure and urinary protein excretion at uniformly scheduled prenatal visits, protocols for monitoring these measurements during the hospitalization for delivery, and reviews of medical records of

unscheduled outpatient visits and all hospitalizations. Results Calcium supplementation did not significantly reduce the incidence or severity of preeclampsia or delay its onset. Preeclampsia occurred in 158 of the 2295 women in the calcium group (6.9 percent) add 168 of the 2294 women in the placebo group (7.3 percent) (relative risk, 0.94; 95 percent confidence interval, 0.76 to 1.16). There were no significant differences between the two groups in the prevalence of pregnancy-associated hypertension without preeclampsia (15.3 percent vs. 17.3 percent) or of all hypertensive disorders (22.2 percent vs. 24.6 percent). The mean systolic and diastolic blood pressures during pregnancy were similar in both groups. Calcium did not reduce the numbers of preterm deliveries, small-for-gestational-age births, or fetal and neonatal deaths; nor did it increase urolithiasis during pregnancy. Conclusions Calcium supplementation during pregnancy did not prevent preeclampsia, pregnancy-associated hypertension, or adverse perinatal outcomes in healthy nulliparous women.

LANGUAGE: ENGLISH SUMMARY LANGUAGE: ENGLISH

Purpose: To report the progress (after 9-year follow-up) of a study designed to determine whether improved glucose control in patients with newly diagnosed non-insulin-dependent diabetes mellitus (NIDDM) is effective in reducing the incidence of clinical complications. Data Source: A multicenter, randomized, controlled trial of different therapies for NIDDM. After initial diet therapy, 4209 asymptomatic patients who remained hyperglycemic (fasting plasma glucose levels, 6.0 to 15.0 mmol/L) were assigned to either a conventional therapy policy, primarily with diet alone, or to an intensive therapy policy, aiming for fasting plasma glucose levels of less than 6.0 mmol/L, with **assignment** to primary therapy with sulfonylurea or insulin (which increased insulin supply) or metformin (which enhanced insulin sensitivity). Results: All three modes of

pharmacologic therapy in the intensively treated group-sulfonylurea, insulin, and metformin-had similar efficacy in reducing the fasting plasma glucose and glycated hemoglobin levels. Over 9 years, patients assigned to intensive therapy with sulfonylurea or insulin had lower fasting plasma glucose levels (median, 7.3 and 9.0 mmol/L, respectively) and lower hemoglobin A(1c) levels (6.7% and 7.5%, respectively) than patients assigned to conventional therapy. Regardless of the assigned therapy, however, the fasting plasma glucose and hemoglobin A(1c) levels increased, and maintaining near-normal glycemia was, in general, not feasible. Even insulin therapy did not achieve the therapeutic goal of near-normal glycemia because of the difficulty in treating marked hyperglycemia and the risk for hypoglycemic episodes. Nine years after the diagnosis of diabetes, 29% of the patients had had a diabetes-related clinical end point, 20% had had a macrovascular complication, and 9% had had a microvascular complication. Conclusions: A report will be published in 1998 after a median duration from randomization of 11 years (range, 6 to 20 years) with an 81% power at a 1% level of significance of detecting whether the obtained improvement in glucose control causes a 15% decrease or increase in the incidence of major complications and whether any specific therapy is advantageous or disadvantageous.

LANGUAGE: ENGLISH SUMMARY LANGUAGE: ENGLISH

Parents in 25 families with a diabetic child in poor metabolic control rated their family climate with a **checklist** containing 85 adjectives constituting four climate factors: Closeness, Distance, Expressiveness, and Chaos. Data were obtained before and after one of three treatment conditions: family therapy, pediatric support, and conventional treatment. Data also were obtained from 12 patients in optimal metabolic control and their families, and from 10 reference families with healthy children. Prior to treatment, the parents of children in poor metabolic control rated their family climate as lower on Closeness and higher on Chaos, as compared with the parents of children in optimal control. No differential effects on family climate were found between the family therapy and pediatric support groups. The combined treatment groups rated themselves as higher on Closeness and lower on Chaos after intervention than before. We concluded that parents with children in poor metabolic control normalize their self-treated family climate following family treatment.

Nonpharmacologic intervention to reduce blood pressure in older patients with mild hypertension

LANGUAGE: ENGLISH SUMMARY LANGUAGE: ENGLISH

Background. - Although nonpharmacologic interventions are widely recommended in the therapy of high blood pressure in older adults, surprisingly little data exist to confirm the efficacy of these interventions in older persons. Methods. - We conducted a randomized, controlled clinical trial in persons aged 60 to 85 years with a diastolic blood pressure of 85 to 100 mm Hg. The experimental arm was a nonpharmacologic intervention combining weight reduction, sodium restriction, and increased physical activity. The nonpharmacologic intervention consisted of eight weekly group and two individual sessions during the intensive phase, followed by four monthly group sessions during the maintenance phase. The control group received no treatment during the study. Blood pressure was assessed by certified technicians (blinded to group assignment) using random zero sphygmomanometers. Results. - Of 56 participants randomized, 47 completed the entire 6-month trial (21 in the intervention group and 26 in the control group). Attendance at the intervention sessions was excellent. The intervention group lost more weight (-2.1 kg) over 6 months than the control group (+0.3 kg). Trends for decreasing 24-hour urine sodium excretion in both the intervention and control groups, with greater trend in the intervention group, were not statistically significant. The intervention group experienced more reduction in systolic and diastolic blood pressure than did the control group (mean differences between groups at 6 months, 4.2/4.9 mm Hg, respectively). Conclusions. - Our data indicate that a nonpharmacologic intervention will lower systolic and diastolic blood pressure levels in older people with borderline or mild elevations of diastolic blood pressure.

Abstract: **Monitoring clinical trials** often requires examining the interim findings to see if the **sample** size originally specified in the protocol will provide the required power against the null hypothesis when the alternative hypothesis is true, and to increase the sample size if necessary. This paper presents a new method, based on the overall response rate, for carrying out interim power evaluations when the observations have binomial distributions, without unblinding the treatment **assignments** or materially affecting the type I error rate. Simulation study results confirm the performance of the method.
